14.2: Self-Inductance and Inductors

Mutual inductance arises when a current in one circuit produces a changing magnetic field that induces an emf in another circuit. But can the magnetic field affect the current in the original circuit that produced the field? The answer is yes, and this is the phenomenon called *self-inductance*.

*Figure* shows some of the magnetic field lines due to the current in a circular loop of wire. If the current is constant, the magnetic flux through the loop is also constant. However, if the current $I$ were to vary with time—say, immediately after switch S is closed—then the magnetic flux $\Phi_m$ would correspondingly change. Then Faraday’s law tells us that an emf $\epsilon$ would be induced in the circuit, where

$$\epsilon = -\frac{d\Phi_m}{dt}.$$ 

Since the magnetic field due to a current-carrying wire is directly proportional to the current, the flux due to this field is also proportional to the current; that is,

$$\Phi_m \propto I.$$
A magnetic field is produced by the current $I$ in the loop. If $I$ were to vary with time, the magnetic flux through the loop would also vary and an emf would be induced in the loop.

This can also be written as

$$\Phi_m = LI$$

where the constant of proportionality $L$ is known as the **self-inductance** of the wire loop. If the loop has $N$ turns, this equation becomes

$$\boxed{N\Phi_m = LI}$$

By convention, the positive sense of the normal to the loop is related to the current by the right-hand rule, so in Figure, the normal points downward. With this convention, $\Phi_m$ is positive in Equation, so $L$ always has a positive value.

For a loop with $N$ turns, $\epsilon = -Nd\Phi_m/dt$, so the induced emf may be written in terms of the self-inductance as

$$\boxed{\epsilon = -L\frac{dI}{dt}}$$

When using this equation to determine $L$, it is easiest to ignore the signs of $\epsilon$ and $dI/dt$, and calculate $L$ as

$$L = \frac{\left|\epsilon\right|}{\left|dI/dt\right|}$$

Since self-inductance is associated with the magnetic field produced by a current, any configuration of conductors possesses self-inductance. For example, besides the wire loop, a long, straight wire has self-inductance, as does a coaxial cable. A coaxial cable is most commonly used by the cable television industry and may also be found connecting to your cable modem. Coaxial cables are used due to their ability to transmit electrical signals with minimal distortions. Coaxial cables have two long cylindrical conductors that possess current and a self-inductance that may have undesirable effects.

A circuit element used to provide self-inductance is known as an **inductor**. It is represented by the symbol shown in Figure, which resembles a coil of wire, the basic form of the inductor. Figure shows several types of inductors commonly used in
In accordance with Lenz’s law, the negative sign in Equation indicates that the induced emf across an inductor always has a polarity that opposes the change in the current. For example, if the current flowing from $A$ to $B$ in Figure(a) were increasing, the induced emf (represented by the imaginary battery) would have the polarity shown in order to oppose the increase. If the current from $A$ to $B$ were decreasing, then the induced emf would have the opposite polarity, again to oppose the change in current (Figure(b)). Finally, if the current through the inductor were constant, no emf would be induced in the coil.

One common application of inductance is to allow traffic signals to sense when vehicles are waiting at a street intersection. An electrical circuit with an inductor is placed in the road underneath the location where a waiting car will stop. The body of the car increases the inductance and the circuit changes, sending a signal to the traffic lights to change colors. Similarly, metal detectors used for airport security employ the same technique. A coil or inductor in the metal detector frame acts as both a transmitter and a receiver. The pulsed signal from the transmitter coil induces a signal in the receiver. The self-inductance of the circuit is affected by any metal object in the path (Figure). Metal detectors can be adjusted for sensitivity and can also sense the presence of metal on a person.
Large induced voltages are found in camera flashes. Camera flashes use a battery, two inductors that function as a transformer, and a switching system or oscillator to induce large voltages. Recall from Oscillations on oscillations that "oscillation" is defined as the fluctuation of a quantity, or repeated regular fluctuations of a quantity, between two extreme values around an average value. Also recall (from Electromagnetic Induction on electromagnetic induction) that we need a changing magnetic field, brought about by a changing current, to induce a voltage in another coil. The oscillator system does this many times as the battery voltage is boosted to over 1000 volts. (You may hear the high-pitched whine from the transformer as the capacitor is being charged.) A capacitor stores the high voltage for later use in powering the flash.

Example : Self-Inductance of a Coil

An induced emf of 2.0 V is measured across a coil of 50 closely wound turns while the current through it increases uniformly from 0.0 to 5.0 A in 0.10 s. (a) What is the self-inductance of the coil? (b) With the current at 5.0 A, what is the flux through each turn of the coil?

Strategy

Both parts of this problem give all the information needed to solve for the self-inductance in part (a) or the flux through each turn of the coil in part (b). The equations needed are Equation for part (a) and Equation for part (b).

Solution

1. Ignoring the negative sign and using magnitudes, we have, from Equation, \[L = \frac{\epsilon}{dI/dt} = \frac{2.0 \ \text{V}}{5.0 \ \text{A}/0.10 \ \text{s}} = 4.0 \times 10^{-2} \text{H}.\]

2. From Equation, the flux is given in terms of the current by \[\Phi_m = LI/N,\] so \[\Phi_m = \frac{(4.0 \times 10^{-2} \ \text{H})(5.0 \ \text{A})}{50 \ \text{turns}} = 4.0 \times 10^{-3} \text{Wb}.\]

Significance
The self-inductance and flux calculated in parts (a) and (b) are typical values for coils found in contemporary devices. If the current is not changing over time, the flux is not changing in time, so no emf is induced.

Note

**Check Your Understanding** Current flows through the inductor in Figure from B to A instead of from A to B as shown. Is the current increasing or decreasing in order to produce the emf given in diagram (a)? In diagram (b)?

[Hide Solution]

a. decreasing; b. increasing; Since the current flows in the opposite direction of the diagram, in order to get a positive emf on the left-hand side of diagram (a), we need to decrease the current to the left, which creates a reinforced emf where the positive end is on the left-hand side. To get a positive emf on the right-hand side of diagram (b), we need to increase the current to the left, which creates a reinforced emf where the positive end is on the right-hand side.

Note

**Check Your Understanding** A changing current induces an emf of 10 V across a 0.25-H inductor. What is the rate at which the current is changing?

[Hide Solution]

40 A/s

A good approach for calculating the self-inductance of an inductor consists of the following steps:

Problem-Solving Strategy: Self-Inductance

1. Assume a current $I$ is flowing through the inductor.
2. Determine the magnetic field $\vec{B}$ produced by the current. If there is appropriate symmetry, you may be able to do this with Ampère’s law.
3. Obtain the magnetic flux, $\Phi_m$.
4. With the flux known, the self-inductance can be found from Equation, $L = N\Phi_m/I$.

To demonstrate this procedure, we now calculate the self-inductances of two inductors.

Consider a long, cylindrical solenoid with length $l$, cross-sectional area $A$, and $N$ turns of wire. We assume that the length of the solenoid is so much larger than its diameter that we can take the magnetic field to be $B = \mu_0 n I$ throughout the interior of the solenoid, that is, we ignore end effects in the solenoid. With a current $I$ flowing through the coils, the magnetic field produced within the solenoid is

\[ B = \mu_0 \left( \frac{N}{l} \right) I \]

so the magnetic flux through one turn is

\[ \Phi_m = BA = \frac{\mu_0 NA}{l} I \]
Using Equation, we find for the self-inductance of the solenoid,

Note

\[ L_{\text{solenoid}} = \frac{N\Phi_m}{I} = \frac{\mu_0N^2A}{l}. \]

If \( n = \frac{N}{l} \) is the number of turns per unit length of the solenoid, we may write Equation as

\[ L = \mu_0 \left( \frac{N}{l} \right)^2 Al = \mu_0 n^2 Al = \mu_0 n^2 (V), \]

where \( (V = Al) \) is the volume of the solenoid. Notice that the self-inductance of a long solenoid depends only on its physical properties (such as the number of turns of wire per unit length and the volume), and not on the magnetic field or the current. This is true for inductors in general.

A toroid with a rectangular cross-section is shown in Figure. The inner and outer radii of the toroid are \((R_1)\) and \((R_2)\), and \((h)\) is the height of the toroid. Applying Ampère’s law in the same manner as we did in [link] for a toroid with a circular cross-section, we find the magnetic field inside a rectangular toroid is also given by

\[ B = \frac{\mu_0NI}{2\pi r}, \]

where \( r \) is the distance from the central axis of the toroid. Because the field changes within the toroid, we must calculate the flux by integrating over the toroid’s cross-section. Using the infinitesimal cross-sectional area element \((da = h \, dr)\) shown in Figure, we obtain

\[ \Phi_m = \int B \, da = \int_{R_1}^{R_2} \left( \frac{\mu_0 NI}{2\pi r} \right) (hdr) = \frac{\mu_0NhI}{2\pi} \ln \frac{R_2}{R_1}. \]

\[ Figure \ \PageIndex{6}: \ Calculating the self-inductance of a rectangular toroid. \]

Now from Equation, we obtain for the self-inductance of a rectangular toroid

Note

\[ L = \frac{N\Phi_m}{I} = \frac{\mu_0N^2h}{2\pi} \ln \frac{R_2}{R_1}. \]
As expected, the self-inductance is a constant determined by only the physical properties of the toroid.

Note

**Check Your Understanding** (a) Calculate the self-inductance of a solenoid that is tightly wound with wire of diameter 0.10 cm, has a cross-sectional area of \((0.90 \, \text{cm}^2)\), and is 40 cm long. (b) If the current through the solenoid decreases uniformly from 10 to 0 A in 0.10 s, what is the emf induced between the ends of the solenoid?

[Hide Solution]

a. \((4.5 \times 10^{-5} \, \text{H})\); b. \((4.5 \times 10^{-3} \, \text{V})\)

Note

**Check Your Understanding** (a) What is the magnetic flux through one turn of a solenoid of self-inductance \((8.0 \times 10^{-5} \, \text{H})\) when a current of 3.0 A flows through it? Assume that the solenoid has 1000 turns and is wound from wire of diameter 1.0 mm. (b) What is the cross-sectional area of the solenoid?

[Hide Solution]

a. \((2.4 \times 10^{-7} \, \text{Wb})\); b. \((6.4 \times 10^{-5} \, \text{m}^2)\)
